Insulated glass units (IGUs) are designed to provide superior thermal and acoustic insulation. They consist of two or more glass panels held together by a spacer, creating a sealed air space. This design significantly reduces heat transfer and sound penetration compared to regular glass. The air space acts as a natural insulator, trapping heat in winter and reflecting it back into the room. Additionally, the multiple layers of glass and the air gap help to dampen sound waves, reducing noise levels. The spacer is typically made of a non-conductive material to further enhance the unit's insulating properties. Overall, IGUs offer a more energy-efficient and quieter environment than single-pane glass.
